1 This application claims the benefit of U.S. Provisional Application Serial No.
2 60/137,615, filed June 3, 1999.

4 BACKGROUND OF THE INVENTION

5 Field of Invention

6 This invention is directed toward antistatic yarns, as well as to the fiber blends
7 from which such yarns are made and the antistatic fabrics and carpets into which such
8 yarns may be incorporated. More specifically, the present invention is directed toward
9 antistatic yarns where about 35 percent or more by weight of all the individual staple
10 fibers present are conductive or quasi-conductive staple fibers.

11 Background

12 It is well known that the generation and uncontrolled discharge of static electrical
13 charge can be problematic in many fields.

14 In one example, static charge can accumulate in flexible containers such as
15 flexible intermediate bulk containers (FIBCs). Containers formed of flexible fabric are
16 used widely in commerce to carry free-flowing materials in bulk quantities. Flexible
17 intermediate bulk containers are typically used to carry and deliver finely-divided solids
18 such as cement, fertilizers, salt, sugar and grains. The fabric from which such FIBCs are
19 generally constructed is a weave of one or more synthetic polymer materials, e.g., a
20 polyolefin such as polypropylene. This fabric may optionally be coated with a similar
21 polymer material on one or both sides. If such a coating is applied, the fabric may
22 become non-porous, while fabric without such coating will usually be porous. The usual
23 configuration of such FIBCs involves a rectilinear or cylindrical body having a wall,
24 base, cover, and a closable spout extending from the base or from the top or both.

25 Crystalline (isotactic) polypropylene is a particularly useful material from which
26 to fabricate monofilament, multifilament or flat tape yarns for use in the construction of
27 woven fabrics for FIBCs. In weaving fabrics of polypropylene, it is the practice to orient
28 the yarns monoaxially. Such yarns may be of rectangular or circular cross-section. This
29 is usually accomplished by hot-drawing, so as to irreversibly stretch the yarns and thereby
30 orient their molecular structure. Fabrics of this construction are exceptionally strong,

1 light-weight, and stable. Examples of such fabrics used in FIBCs are well-known in the
2 art and are disclosed in U.S. Pat. Nos. 3,470,928; 4,207,937; 4,362,199 and 4,643,119.

3 It has long been observed that static electrical charge can accumulate in FIBCs
4 and other containers. This accumulation is thought to take place as a result of the shifting
5 and other movement between particles and between particles and the walls of the
6 container. For example, the generation of static charge has been observed on the walls
7 and in the contents of FIBCs during the filling, unfilling, and movement of such
8 containers. This accumulation has also been observed to take place to a greater extent in
9 environments of lower relative humidity.

10 Discharges of accumulated static electrical charge may be dangerous if they are of
11 sufficient energy to be incendiary. That is, a discharge of sufficient energy may be able
12 to initiate the ignition of combustible materials present in dusty atmospheres or
13 flammable vapor atmospheres. Discharges of accumulated static charge may also be
14 uncomfortable to workers handling such containers.

15 In another example, static electrical charge is known to be generated and
16 transferred to a person walking on conventional carpet structures. When the person
17 walking across such surfaces later becomes grounded, accumulated charge flows through
18 that part of the person's body which by chance comes in contract with the grounded
19 object. When the grounded object is a metal door knob or metal cabinet, the resulting
20 electrical shock can be discomforting to many people. When the grounded object is a
21 computer or other electronic equipment, the resulting discharge can permanently damage
22 the sensitive electronic and microelectronic components contained within these devices.

23 In a third example, undesired static charge is known to build up in the fabric of
24 many types of apparel. Such accumulated static electrical charge may cause a garment to
25 cling to itself and other adjacent articles of clothing, resulting in annoyance of the wearer.
26 Such charge is also thought to accelerate the soiling of the garment by attracting airborne
27 dust and dirt. Moreover, in order to prevent damage to sensitive electronic and
28 microelectronic parts during their manufacture and processing, there continues to be a
29 real need to minimize static charge on apparel for work uniforms worn by people in the

1 electronics industry. Also, the accumulation of static electrical charge must be minimized
2 on apparel worn by people working within potentially explosive environments.

3 Other examples of the problems associated with the unwanted accumulation of
4 static electricity are readily known to those skilled in the art.

5 There continues to exist a real need for improved yarns, fabrics, fabric containers
6 and carpets that are capable of effectively preventing the accumulation and resulting
7 high-energy discharge of static electrical charge.

8 9 SUMMARY OF THE INVENTION

10 The present invention is generally related to antistatic yarns, as well as to the fiber
11 blends from which such yarns are made and the antistatic fabrics and carpets into which
12 such yarns may be incorporated. More specifically, the present invention comprises
13 antistatic yarns whereby about 35 percent or more by weight of the staple fibers present
14 are conductive, quasi-conductive staple fibers, or mixtures of conductive and quasi-
15 conductive staple fibers.

16 In one set of embodiments of the present invention, the antistatic yarn contains
17 staple fibers whereby about 35 percent or more by weight of the staple fibers present are
18 conductive staple fibers. Suitable conductive staple fibers include metal staple fibers,
19 metal-coated non-conductive polymer staple fibers, carbon-loaded polymer staple fibers,
20 polymer staple fibers loaded with antimony-doped tin oxide, conductive polymer
21 solution-coated non-conductive polymer staple fibers, inherently-conductive polymer
22 staple fibers, and bicomponent staple fibers.

23 In a second set of embodiments of the present invention, the antistatic yarn
24 contains staple fibers whereby about 35 percent or more by weight of the staple fibers
25 present are quasi-conductive staple fibers, including bicomponent quasi-conductive staple
26 fibers.

27 In a third set of embodiments of the present invention, the antistatic yarn contains
28 staple fibers whereby about 35 percent or more by weight of the staple fibers present are a
29 mixture of conductive staple fibers and quasi-conductive staple fibers.

1 In each of the above three sets of embodiments of the present invention, the
2 antistatic yarn may also contain continuous fibers and/or non-conductive staple fibers.

3 In still other embodiments of the present invention, the above antistatic yarns are
4 present in antistatic fabrics and carpets. Further still, in another embodiment of the
5 present invention, the antistatic yarns are present in flexible intermediate bulk containers.
6

7 DETAILED DESCRIPTION OF THE INVENTION AND CERTAIN 8 ILLUSTRATIVE EMBODIMENTS

9 This invention is directed towards antistatic yarns, as well as to the fiber blends
10 from which such yarns are made and the antistatic fabrics and carpets into which such
11 yarns may be incorporated. The present invention more specifically comprises antistatic
12 yarns where about 35 percent or more of the individual staple fibers present are
13 conductive staple fibers, quasi-conductive staple fibers, or a mixture of conductive and
14 quasi-conductive staple fibers. It will be understood that the term "yarn," as used herein,
15 is employed consistent with its ordinary meaning to those skilled in the art and may
16 comprise one fiber or two or more individual fibers twisted together in such a way as to
17 enable the yarn to be subject to further physical manipulation. Likewise, it will be
18 understood that the terms "staple" and "continuous," as applied to the fibers from which
19 yarns may be manufactured, are employed consistent with their ordinary meaning to
20 those skilled in the art. Moreover, the art is well-versed in suitable methods of combining
21 different types of staple fibers, as well as combining staple fibers and continuous fibers,
22 to form suitable yarns having predictable physical strength and elongation properties. An
23 overview of such combination techniques is provided in Hudson, Peyton B., *et al*,
24 *Joseph's Introductory Textile Science*, 6th ed., Ch. 16, 1993, Harcourt Brace Jovanovich
25 College Publishers, N.Y., the disclosure of which is incorporated herein by reference.

26 First Set of Embodiments

27 In a first embodiment of the present invention, the antistatic yarn is made entirely
28 from staple fibers. According to this embodiment, about 35 percent or more by weight of
29 fibers are conductive staple fibers. The balance of staple fibers, if any, may be non-
30 conductive staple fibers. Standard processing techniques commonly used to manufacture

002090" T0298560

1 spun yarn from different types of staple fibers, for example, ring spinning, may be
2 employed to make antistatic yarn according to this embodiment.

3 Conductive staple fibers, as used herein, include those fibers in which each
4 individual fiber has a direct current (DC) linear resistance of less than about 10^9 ohms per
5 centimeter. Suitable conductive staple fibers include metal staple fibers, metal-coated
6 non-conductive polymer staple fibers, carbon-loaded polymer staple fibers, polymer
7 staple fibers loaded with antimony-doped tin oxide, conductive polymer solution-coated
8 non-conductive polymer staple fibers, inherently-conductive polymer staple fibers, and
9 bicomponent conductive staple fibers.

10 Suitable metal staple fibers include those made from stainless steel, copper,
11 aluminum, steel, iron, tin, brass, or other metallic materials. Other suitable conductive
12 staple fibers include those made from metal-coated fibers of non-conductive polymer.
13 An example of such fibers is the silver-coated nylon fiber product made and sold by
14 Sauquoit Industries of Scranton, Pennsylvania. While metal and metal-coated non-
15 conductive polymer staple fibers are suitable for the present invention, they typically
16 have very low electrical linear resistances and have a tendency to produce high-energy
17 spark discharges rather than the low-energy discharges characteristic of carbon-loaded
18 conductive fibers. Thus, metal and metal-coated non-conductive polymer staple fibers
19 are less preferred.

20 Preferred conductive staple fibers include those made from carbon-loaded
21 polymer. The techniques and methods used to introduce carbon (graphite) into a
22 normally non-conductive polymer, such as, for example nylon, are well known in the art.
23 Such introduction of carbon reduces the resistivity of the resultant carbon-loaded
24 polymer. In this way, the introduction of, for example, about 10 to 35 weight percent
25 carbon, or more preferably 25 to 32 weight percent carbon into the polymer will yield a
26 suitable material that may be used to form conductive carbon-loaded polymer fibers. It
27 will be understood that carbon may be added to other suitable normally non-conductive
28 polymers, such as polypropylene and polyester, to make carbon-loaded polymer fibers,
29 and that these and other carbon-loaded polymer fibers are within the scope of the present

1 invention. Suitable carbon-loaded conductive staple fibers are widely commercially
2 available from a variety of manufacturers.

3 Still other suitable conductive staple fibers include those made from polymer
4 loaded with antimony-doped tin oxide. The techniques and methods used to introduce
5 the antimony-doped tin oxide into a normally non-conductive polymer are also well
6 known in the art. The antimony-doped tin oxide typically used for this purpose is in the
7 form of a fine powder antimony-doped tin oxide or titanium dioxide powder coated with
8 antimony-doped tin oxide. The antimony doping renders the semi-conductive tin oxide
9 conductive, and the addition of about 50 to 75 weight percent of antimony-doped tin
10 oxide is typically sufficient to render the so loaded polymer conductive. It will be
11 understood that other materials, including other electrically-conductive pigments, may
12 also be loaded into a normally non-conductive polymer to render it conductive, and that
13 conductive staple fibers made from such polymers are within the scope of the invention.
14 However, the electrical properties of conductive polymer blends made using antimony-
15 doped tin oxide and other materials may not be as good as those made using carbon.
16 Thus, carbon-loaded polymers are preferred over polymers made conductive by loading
17 with antimony-doped tin oxide or other materials.

18 Other suitable conductive staple fibers include those made by coating a normally
19 non-conductive polymer fiber with a solution containing a conductive polymer. Suitable
20 solutions include those containing polyaniline and polypyrrole. Polyaniline-containing
21 solutions are preferred. The techniques and methods used to coat the non-conductive
22 polymer fibers, making the resultant coated fibers conductive, are well known in the art.

23 Still other suitable conductive staple fibers include those made using inherently-
24 conductive polymer. Inherently-conductive polymers, also commonly termed
25 intrinsically-conductive polymers, are well known in the art and include polyaniline and
26 polypyrrole. Polyaniline is preferred. A plasticized polyaniline complex supplied by
27 Panipol Oy of Finland can be used to make conductive polymer blends using known melt
28 processing techniques. Another supplier of polyaniline, although not in the form of a
29 melt-processible polyaniline complex, is Ormecon of Germany.

002090" 090200

Further still, other suitable conductive staple fibers include those fibers that are conductive bicomponent staple fibers. The term "bicomponent" as used herein to reference fibers includes all fibers, whether in staple or continuous form, made by placing at least two longitudinally-extending constituents in intimate longitudinal contact with each other, the first longitudinally-extending constituent formed of at least one fiber-forming non-conductive polymer and the second longitudinally-extending constituent formed of at least one conductive material. Suitable fiber-forming non-conductive polymers include nylon, polypropylene and polyester. Suitable conductive materials include carbon-loaded polymers, polymers loaded with antimony-doped tin oxide, inherently-conductive (intrinsically-conductive) polymers, and metals. Carbon-loaded polymers and inherently-conductive polymers are preferred.

It will be understood by those of ordinary skill in the art that the term "bicomponent fiber" embraces a union of longitudinally-extending constituents in a variety of configurations. In one example, the first longitudinally-extending constituent may form a core and the second longitudinally-extending constituent a sheath such that the first constituent is completely encased by the second. Since in this example, the outer "shell" or sheath material (*i.e.*, the second longitudinally-extending constituent) is electrically-conductive, the fiber as a whole will be conductive.

In a second example of a bicomponent fiber, the first longitudinally-extending constituent may be only partially encased or ensheathed by the second. In this case also, the presence of the conductive second longitudinally-extending constituent on the surface of the fiber will cause the fiber as a whole to be conductive.

In a third example, the (conductive) second longitudinally-extending constituent may take the form of at least one longitudinal stripe partially encapsulated within the first longitudinally-extending constituent. The term "partially encapsulated" as used herein means that at least part of second longitudinally-extending constituent is exposed on the outer surface of the fiber. Such fibers are often called "racing stripe" fibers and are commercially available, for example from Solutia, Inc. Such racing stripe fibers may contain from 1 to 5 or more such longitudinal stripes. Fibers made under this example will also be conductive fibers.

002090.T0298560

1 In a fourth example, the (non-conductive) first longitudinally-extending
2 constituent may form a sheath completely or almost completely encasing the (conductive)
3 second longitudinally-extending constituent. In this case, measurements of the direct
4 current linear resistance of the fiber become difficult. This is because the measurement
5 probes may sometimes only contact the outer non-conductive shell of the fiber (yielding a
6 linear resistance measurement consistent with a non-conductive fiber), and at other times
7 contact the inner conductive core or the fiber (yielding a linear resistance measurement
8 consistent with a conductive fiber). Such bicomponent fibers, having a sheath of non-
9 conductive material completely or almost completely encasing a core of conductive
10 material, are commonly termed "quasi-conductive" fibers.

11 Such bicomponent conductive and quasi-conductive fibers are well-known in the
12 art and are disclosed, for example in U.S. Patents 3,969,559 to Boe and 5,202,185 to
13 Sammuelson. Bicomponent conductive and/or quasi-conductive fibers are also readily
14 available from Solutia, Inc. (under its "No-Shock"® brand), Dupont, BASF and Kanebo
15 of Japan.

16 The first embodiment of the present invention, which as noted above includes
17 suitable bicomponent conductive staple fibers, thus includes the bicomponent staple
18 fibers described in the above first, second, and third examples.

19 In a second embodiment of the present invention, antistatic yarn is made by
20 combining staple fibers and continuous fibers. According to this embodiment, about 35
21 percent or more by weight of the staple fibers present are conductive staple fibers.
22 Friction spinning, modified to allow the wrapping of a center fiber core with other fibers,
23 (a form of "core spinning") is one suitable processing technique that may be used. Thus
24 according to the present invention, there is formed a yarn having a core of continuous
25 fibers surrounded by a sheath of staple fibers. Such yarns are among those commonly
26 termed "core spun" yarns. The above modified friction spinning techniques, as well as
27 other techniques for combining staple and continuous fibers, are well-known in the art.

28 The relative proportions of staple fibers and continuous fibers may vary greatly.
29 These proportions are dictated by factors such as the desired strength and other physical
30 properties of the antistatic yarn, the desired amount of static charge dissipation capability,

1 somewhat different from those having an outer sheath of a conductive material. Also, the
2 use of quasi-conductive staple fibers alone or in conjunction with conductive staple fibers
3 will afford some control over the linear resistance of the resultant yarn, thereby helping to
4 minimize or eliminate incendiary static discharges.

5 In another embodiment of the present invention, antistatic yarn is made by
6 combining staple fibers and continuous fibers. According to this embodiment, about 35
7 percent or more by weight of the staple fibers present are quasi-conductive staple fibers.
8 Again, as with the First Set of Embodiments discussed above, standard processing
9 techniques such as modified friction spinning may be employed, and the relative
10 proportions between the staple fibers and the continuous fibers may be varied greatly.
11 Again, any suitable continuous fibers may be used, including conductive fibers, quasi-
12 conductive fibers, and non-conductive fibers. For the reasons disclosed above,
13 continuous conductive fibers are thought to be preferred.

14 Third Set of Embodiments

15 In another embodiment of the present invention, the antistatic yarn is made
16 entirely from staple fibers, wherein about 35 percent or more by weight of the fibers are a
17 mixture of conductive and quasi-conductive fibers. The balance of staple fibers, if any,
18 may be non-conductive staple fibers. As with the First Set of Embodiments discussed
19 above, standard processing techniques may be employed.

20 Once again, the use of some quasi-conductive staple fibers may offer advantages
21 in terms of ease of processing the fiber blend into yarn and affording some control over
22 the linear resistance of the resultant yarn.

23 In still another embodiment of the present invention, antistatic yarn is made by
24 combining staple fibers and continuous fibers. According to this embodiment, about 35
25 percent or more by weight of the staple fibers present are a mixture of conductive and
26 quasi-conductive fibers. Once again, standard spinning techniques may be employed, the
27 relative proportions between the staple fibers and the continuous fibers may be varied
28 greatly, and any suitable continuous fibers may be used, including conductive fibers,
29 quasi-conductive fibers, and non-conductive fibers. For the reasons disclosed above,
30 continuous conductive fibers are here again thought to be preferred.

002090" 10298550

1 A reference yarn consisting of bicomponent conductive continuous fibers was
2 prepared using standard techniques. The yarn consisted of 40 filaments and had a denier
3 of 350. The bicomponent fibers consisted of a sheath of conductive polymer (nylon
4 loaded with about 30 percent by weight carbon) completely surrounding a core of non-
5 conductive nylon.

6 Example 2

7 An antistatic yarn according to this invention, consisting of 50 weight percent
8 conductive staple fibers and 50 weight percent non-conductive nylon staple fibers, was
9 produced via a standard ring-spinning technique. The conductive staple fibers were
10 obtained starting from an 18 denier, 2 continuous fiber yarn, wherein each filament was a
11 bicomponent conductive "racing stripe" fiber having 3 longitudinal stripes of a carbon-
12 loaded conductive polymer constituent on the surface of a non-conductive nylon
13 constituent ("No-Shock"® product no. 18-2E3N yarn, available from Solutia, Inc.). This
14 starting material was twice drawn, to 4.5 denier per filament, and then cut to a fiber
15 length of 1.5 inches before being ring spun with the non-conductive nylon staple fibers
16 (3.5 denier, 1.5 inch fiber length). The total denier of the antistatic yarn was 471.

17 Example 3

18 An antistatic yarn according to this invention, consisting of a core of continuous
19 conductive fibers surrounded by a sheath of conductive staple fibers, was produced via a
20 standard DREF core spinning technique. Equal portions by weight of core continuous
21 fibers and sheath staple fibers were used. The core continuous conductive fibers were the
22 same bicomponent conductive-sheath, non-conductive core fibers described in Example
23 1. The surrounding conductive staple fibers were the same twice-drawn 4.5 denier per
24 filament, 1.5 inch cut length, 3-"racing stripe" fibers described in Example 2. The total
25 denier of the formed antistatic yarn was 632.

26 Example 4

27 An antistatic yarn according to this invention, consisting of a core of continuous
28 conductive fibers surrounded by a sheath of staple fibers was produced via standard core
29 spinning techniques. Again, equal portions by weight of core continuous fibers and
30 sheath staple fibers were used. The core continuous conductive fibers were again the

same bicomponent conductive-sheath, non-conductive core fibers described in Example 1. The surrounding staple fibers consisted of the 50/50 blend of conductive and non-conductive staple fibers used in Example 2. The total denier of the formed antistatic yarn was 616.

Test Results

Table I below shows some of the physical properties of the exemplary antistatic yarns made according to the present invention. These yarns have physical properties suitable for incorporation into fabrics, carpets, and other items.

Table I

Antistatic Yarn	Denier	Break Strength (G)	Elongation at Breaking (%)	Linear Resistance of Yarn (ohm/cm)
Example 2	471	912	28.5	5.5×10^9
Example 3	632	703	45.9	5.9×10^5
Example 4	616	927	28.3	3.6×10^5

In one experiment to test the antistatic properties of the present invention, the static dissipation time of the antistatic yarn of Example 2 was measured. Test conditions were 23 degrees Celsius and 50 % relative humidity. A length of the sample yarn (about 0.5 meters) was prepared by manually wrapping it around a non-conductive piece of polypropylene FIBC fabric in such a way that the sample yarn coils did not touch each other, but rather were spaced about 1 centimeter apart from each other. The sample yarn was then charged to 5000 volts. Next, the sample yarn was grounded, and an electrostatic voltmeter was used to measure the time required for the electric field around the sample yarn to decay to 10 percent of its initial value. Static decay time measurements were made using a Static Decay Meter model 406 D from Electrotech Systems, Inc., Glenside,

002090.T090560

1 PA 19038. This method is consistent with Federal Test Method Standard 101B, Method
2 4046.

3 The antistatic yarn of Example 2 was found to have a static dissipation time of
4 0.01 seconds or less. This compares with a typical static dissipation time of several
5 minutes or more for yarns made solely from non-conductive fibers. This shorter static
6 dissipation time it thought to be surprisingly short, given the yarn's relatively high linear
7 resistance. This combination of short static dissipation time and relatively high linear
8 resistance is a good combination of properties. That is, the short static dissipation time is
9 indicative of the yarn's ability to dissipate static electricity quickly via lower-energy,
10 non-incendiary discharges, and the relatively high linear resistance is indicative of the
11 yarn's ability to dissipate static electricity without producing dangerous higher-energy,
12 sparking discharges.

13 In another experiment to test the antistatic properties of the present invention, the
14 "corona current" of the exemplary yarns was measured as a function of applied voltage.
15 This test was performed by first placing a one-inch length of the sample yarn into a
16 grounded Faraday cup, the upper end of the sample yarn being attached to a high voltage
17 source and the lower end of the sample yarn hanging about 0.25 inches above the bottom
18 of the cup. The cup was connected to ground through a sensitive current meter. Various
19 voltages were applied across the yarn, and the current traveling from the yarn across the
20 air gap to the cup was measured. A more detailed description of this test apparatus and
21 its operation may be found in the following reference, the disclosure of which is
22 incorporated herein by reference: Kessler, LeAnn and Fisher, W. Keith, "A study of the
23 electrostatic behavior of carpets containing conductive yarns," J. Electrostatics, 39 (1997)
24 pp. 260-261.

25 Voltages of up to 5000 volts were applied, and the "corona current" flowing from
26 the sample yarn across the air gap was observed and recorded.

27 Table II shows the results for the exemplary antistatic yarns. Test conditions were
28 23.8 degrees Celsius and 55 % relative humidity. The test apparatus was also operated
29 without a yarn in order to "leak test" the apparatus. Under this condition, it was found
30 that only small quantities of current would flow between the high voltage source and the

grounded Faraday cup. For each applied voltage, the "corrected" current shown in Table II was calculated by subtracting the leak current from the current measured.

Table II

Antistatic Yarn	Applied Voltage: 4000 V		Applied Voltage: 5000 V	
	Measured Current (amps)	Corrected Current (amps)	Measured Current (amps)	Corrected Current (amps)
None (leak test)	0.1×10^{-4}	N/A	0.15×10^{-4}	N/A
Example 1	0.1×10^{-3}	0.9×10^{-4}	0.22×10^{-3}	0.205×10^{-3}
Example 2	0.4×10^{-4}	0.3×10^{-4}	0.7×10^{-4}	0.55×10^{-4}
Example 3	0.1×10^{-3}	0.9×10^{-4}	$\gg 1.0 \times 10^{-3}$	$\gg 1.0 \times 10^{-3}$
Example 4	0.45×10^{-4}	0.35×10^{-4}		

The yarn of Example 2 showed significant corona current, despite its high linear resistance. The yarn of Example 2 also exhibited a visible glow from its fiber ends at an applied voltage above about 4500 volts when the laboratory lights were turned out.

At lower applied voltages, the yarns of Examples 3 and 4 demonstrated corona currents similar to those of yarns made entirely from conductive continuous fibers.

However, small current spikes, measuring up to about 0.1×10^{-3} amps, were observed in the yarn of Example 4 as the applied voltage was increased above about 3000 volts. Very strong current spikes, measuring up to about 2×10^{-3} amps, were observed in the yarns of Examples 3 and 4 at applied voltages between 4000 and 5000 volts. It is thought that these current spikes are associated with the onset of a strong corona discharge along the entire length of the antistatic yarn. Thus, it is thought that these core-spun yarns, having cores of conductive continuous filaments and sheaths of conductive staple fibers, may be particularly useful yarns for many antistatic applications.
